ABSTRACT

This report presents the results of analyses of atmospheric carbon dioxide and ecological factors at Meade River Camp and at North Meadow Lake (Barrow), Alaska. The data summarize reference gas calibrations used in the CO₂ program, with a discussion of methods used to obtain the data for CO₂ concentrations in air at both stations. Variations of CO₂ in the air, at the ground level, and at 16 m above the ground are given for both the Meade River Station and North Meadow Lake. Meteorological observations are presented for the period of observations. The percent rate of growth of five species of tundra plants is shown, and the correlation between CO₂ concentration in the atmosphere and the percent of maximum ground is given. The data for the amounts of chlorophyll and dry weight production in each of four types of communities are presented. A list of publications resulting from the interpretation of these data is included.

I. INTRODUCTION

This report is a record of the data for measurements of carbon dioxide in the atmosphere near the ground and ecological observations during the summer of 1966 at two field stations separated by approximately 1° of latitude. Observations were made throughout the growing season on the Arctic coastal plain of Alaska. The North Meadow Lake Station at an elevation of 6 m (71°18'N, 159°39'W) was 2 km south of the Arctic Ocean and the Navy Arctic Research Laboratory, Barrow, Alaska (Figure 18a). Atmospheric carbon dioxide has been monitored at this station from 1961 to 1967.

The Meade River Station at an elevation of 15 m (70°28'N, 157°26'W) is 110 km SSW of Barrow and was operated from 24 May to 9 September, 1966 (Figures 1 and 2). The terrain is of low relief between the two stations and contains numerous lakes and graminoid tundra vegetation of low stature. No permanent settlements or sources of atmospheric pollution occur between the two stations.

The data in this report are presented in two sections. The first section describes the carbon dioxide data observed at North Meadow Lake and at Meade River. The second section presents environmental and ecological data which documents the results of meteorological observations and measurements which support the progression of plant growth during the period of seasonal thaw. These results therefore extend from the beginning of snow melt in late May thru the growing season of approximately 80 days to the period of freezeup in early September.

Interpretations of these data have been published as reports and journal contributions and the references cited in the Bibliography should be consulted for an expansion of methodology, data synthesis and significance.

II CARBON DIOXIDE OBSERVATIONS

The tables pertaining to carbon dioxide measurements are arranged in such a way that it is possible to progress from the initial calibration of reference gases to final summaries of air CO_2 concentrations. This report does not include hourly values of CO_2 for Meade River Camp or for Barrow. These values are too numerous to tabulate and are documented fully on computer output sheets.¹ The data on the computer sheets are given in index form, that is, provisional parts per million by volume. Conversion to the manometric form, should it be necessary to use these data on an hourly basis, is accomplished by the following equation:

$$\text{MANOMETRIC CONCENTRATION} = (C - 311.51) \times 1.2186 + 311.51 \quad (1)$$

where C is the index value.

In further discussions frequent reference will be made to Technical Report No. 2, An Analysis of Carbon Dioxide in the Arctic Atmosphere at Barrow, Alaska During 1961-62-63 by John J. Kelley, Jr., July 1966. Details of instrumentation and calibration are discussed in this report. Henceforth, reference to this report will be CO_2 Report, 1966. For example, reference to the manometric equation is given in the CO_2 Report, 1966 on page 14.

Explanation of Tables

TABLE 1

This Table presents the results of all calibrations at Meade River accomplished by the Mutual Comparison Method used at the University of Washington. These data again appear in the graph at the end of TABLE 6. This table follows the format of TABLE 2 in the CO_2 Report, 1966.

¹Computer output sheets and data cards are presently located at the Institute of Marine Science, University of Alaska, College, Alaska, 99701.

Reference Cylinder 5752 was chosen as the Primary (I_o), 0221 as the Span (I_s), and 7055 as the Secondary (II). The choice of 5752 as the primary was unfortunate as it appeared to have the least number of calibrations and showed the most drift, however, analytical precision at the Meade River Station was better than 1 ppm.

TABLE 2

Summaries of Recorder Scale Factors are based on single set evaluations. These values are arranged in periods which seem to have the greatest internal continuity. The data are selective in that the original data showed single set values exhibiting values for any one period departing greatly from the average for the period. These come under the heading of "anomalous values" and since they would seriously affect the air data, they are not used. Thus, extreme values resulting from measurement malfunction or temporary air contamination were removed from the calibration.

TABLE 3

TABLE 3 summarizes the mutual comparison recorder scale factors and is similar to CO₂ Report, 1966 TABLE 4.

TABLE 4

Final values for all CRREL² reference cylinders are tabulated and are similar to CO₂ Report, 1966 Tables 5, 6, and 7. Note the fairly wide variation in concentrations with time. University of Washington cylinders generally did not exhibit such wide variations. It is possible that these

²U.S. Army Cold Regions Research and Engineering Laboratory, Hanover, New Hampshire.

variations are a result of old gas cylinders which tend to pick up moisture and small quantities of organic coatings on the inside of the cylinder. These differentially outgas during the life of the tank and produce erratic depletions or additions to the contents of the cylinder. New chrome, molybdenum steel cylinders which have been cleaned and leaked before filling should eliminate this problem of outgassing.

TABLE 5

Index differences used in the computation of recorder scale factors are listed.

TABLE 6

This Table provides a list of sliding recorder scale factors similar to CO₂ Report, 1966 TABLE 5. All values were corrected to 30" Hg (10.16 centibars). The procedure for reducing these data is given in CO₂ Report, 1966.

TABLE 7

Sliding recorder scale factors (RSF) are presented for the North Meadow Lake data during the period of analysis. There is much less variation in the RSF for Barrow than for Meade River. The variation at Barrow (NML) is 0.3 RSF units; at Meade River it varied about 1.8 units.

TABLE 8

Average daily concentrations of atmospheric CO₂ at the 16 meter datum level at Meade River and North Meadow Lake are given. The air indices are taken from the computer output summaries. Manometric air concentrations are calculated according to the formula. (See CO₂ Report, 1966). The data are plotted for North Meadow Lake and Meade River in Figures 3 and 4.

It will be noticed that the variations at North Meadow Lake closely follow those at Meade River. The summer low appears to occur in September during the 1966 season, rather than late August as in the five preceding years.

The period of maximum change in CO_2 concentrations occurs between late June and early July at both stations and is the period of maximum tundra growth. There is an apparent three-day phase lag between the two sites near the inflection point in the curves with Barrow lagging Meade River. Snow melt and plant growth was slower at Barrow than at Meade River.

TABLE 9

Summaries of the weekly averages of CO_2 in the air at 16 meters are given and plotted in the histograms shown in Figures 4 and 5.

Early in the season Meade River showed somewhat higher values than Barrow indicating that the snow is gone and there is both production of CO_2 and initial CO_2 utilization by the early tundra vegetation. During May and June the Barrow area was still snow covered.

The highest differences between the two sites occurred during the week of July 4, and was 2.6 ppm, with Meade River now lower than Barrow.

TABLE 10

Monthly values for CO_2 at Meade River and Barrow are presented.

The following mean monthly differences in CO_2 measured at 16 m above the ground between the two stations was noted:

<u>Month</u>	<u>MR - NML</u>
June	+0.3 ppm
July	-1.8
August	+1.0

These data indicate a net flux of CO_2 from the tundra at Meade River in June, a net utilization in July, and a net utilization for Barrow in August.

TABLE 11

Assuming a constant wind blowing from a given direction and a changing plant growth rate it should be possible to estimate effects of horizontal advection of CO_2 near the ground. It is difficult to obtain a preferred wind orientation at both Meade River and Barrow simultaneously; however, a selection of CO_2 data for winds of 15° and 195° with indicated tolerances are presented in TABLE 11.

The long term average shows almost no horizontal changes along the NML-MR CO_2 transect with wind orientation by our techniques. The greatest detectable differences occurred in early July.

TABLE 12

The distribution of CO_2 near the ground is given. These data are taken from the original computer output sheets. Graphs of the data appear at the end of the section (Figure 7 and 8).

It is immediately seen that during late May and early June at North Meadow Lake, the ground CO_2 values were high. This is accounted for by the fact that these measurements were made under a cover of snow where accumulation occurs due to changing microbiological conditions in the winter, and perhaps physical changes in the active layer of the permanently frozen ground (Kelley et al., 1968).

There was a growing season phase lag of about 3 days occurring during early July. From mid-July to early August the concentrations of CO₂ at Barrow and Meade River were nearly the same, while in late August and September the phase is reversed with Barrow showing effects of net utilization of CO₂ by tundra.

TABLE 13

Weekly average concentrations of CO₂ at ground level are given. The data were averaged to end each series on a Saturday corresponding to weekly vegetation measurements at Meade River. These data are shown graphically in Figures 9 and 10.

High values occurred at Barrow until June 28. This was due to CO₂ entrained under the snow cover. At Meade River ambient CO₂ showed values commensurate with the usual spring rise in CO₂ concentration. The phase lag discussed in the description of Table 12 is seen with the crossover between Meade River and Barrow occurring early to mid-July. After this period growing season of the Barrow area accelerated and utilized more CO₂ from the atmosphere near the ground than Meade River; thus, the higher Meade River CO₂ levels.

TABLE 14

This Table gives the monthly averages for CO₂ near the ground at Meade River and Barrow. Note that the June average is not used because of the anomalously high values at Barrow caused by CO₂ measurements underneath the snow.

TABLE 15

Three-day running means of CO_2 at Meade River and North Meadow Lake at 16 m are represented in Figures 11 and 12.

The major variations in atmospheric CO_2 at 16 m between Meade River and Barrow were:

<u>Date</u>	<u>MR-NML</u>
June 2	+2.1 ppm
14	+2.3
26	-1.0
July 4	-1.5
20	-2.1
28	-0.6
August 20	+0.8
28	+2.9

In early July a three-to four-day lag was noted with Barrow lagging Meade River.

TABLE 16

Six-day running means of CO_2 concentration at 16 m are given.

TABLE 17 and 18

Diurnal variations of CO_2 16 m above the ground are given for the Meade River Station (Table 17) and at North Meadow Lake (Table 18) and are shown in Figures 13 and 14. It was expected that respiration at night and assimilation during the day would cause a higher CO_2 concentration during the night and lower CO_2 concentrations during the late afternoon. This variation is seen for the months of July and August, but not for June 1966.

at Meade River. North Meadow Lake shows the expected diurnal variation for all three months.

TABLE 19

Three month combined averages of the diurnal course of CO₂ for June, July and August 1966 for Meade River and Barrow are tabulated and shown in Figures 15, 16.

Figure 15 shows that minimum CO₂ concentrations occur during the mid- or late afternoon at N.M.L. with an 0.8 ppm change. Meade River shows a diurnal variation with the minimum occurring during the late evening with a maximum variation of 1.5 ppm.

TABLE 20

Carbon dioxide differences between the ground and 16 meter level above the ground are shown for the North Meadow Lake and Meade River Station. The data for both stations are plotted in Figure 17.

III ECOLOGICAL OBSERVATIONS

Results of measurements of biotic and abiotic parameters are presented in the following section. Discussion of methods of analysis and plant taxonomy has been published in several journal contributions (1, 2, 3, 7) previously listed.

Net primary production above ground was harvested each month from 2 x 5 dm plots in the five predominant communities (Figures 34-39). The litter and non-functional plant materials were separated from the chlorophyllous tissue and both components were oven dried at 70° C and weighed. Growth rates of five common species were determined from weekly measurements of stem and inflorescence length on the same 140 plants throughout the summer. For purposes of comparison the data are expressed as percentages of maximum growth. Six day running means of carbon dioxide concentration were compared with percent maximum growth, measured weekly and are shown in Figure 40. Dry matter production in the Arctic ecosystem at Meade River, Alaska is shown in Figure 30. Histograms of chlorophyll distribution in four communities is given in Figure 41. Tables 25 through 33 tabulate information on growth rate, chlorophyll, and dry weight production.

Hourly carbon dioxide concentrations and air temperatures at Meade River for various periods during the growing season are shown in Figures 21-25. The shaded area between the 16 cm and 1 cm curves represents the time and intensity of a positive flux due to photosynthesis at Meade River.

Results of meteorological observations are given in Tables 21, 22, and 23 and Figures 26, 27, 28, and 29. Some chemical analyses of Meade River water samples are given in Table 24.

ACKNOWLEDGMENTS

This work was supported by both 1) the Department of Atmospheric Sciences, University of Washington under the Office of Naval Research Contract (NR 307-252, Contract NONR 477 (24)) and 2) U. S. Army Cold Regions Research and Engineering Laboratory, Hanover, New Hampshire. The work in the field at North Meadow Lake and at Meade River was logistically supported by the Naval Arctic Research Laboratory, Barrow, Alaska. This summary of Arctic data is a contribution to the Tundra Biome Program of the International Biological Program.

13. ABSTRACT		
<p>This report presents the results of analyses of atmospheric carbon dioxide and ecological factors at Meade River Camp and at North Meadow Lake (Barrow), Alaska. The data summarize reference gas calibrations used in the CO₂ program, with a discussion of methods used to obtain the data for CO₂ concentrations in air at both stations. Variations of CO₂ in the air, at the ground level, and at 16 m above the ground are given for both the Meade River Station and North Meadow Lake. Meteorological observations are presented for the period of observations. The percent rate of growth of five species of tundra plants is shown, and the correlation between CO₂ concentration in the atmosphere and the percent of maximum ground is given. The data for the amounts of chlorophyll and dry weight production in each of four types of communities are presented. A list of publications resulting from the interpretation of these data is included.</p>
